

# Huffman Coding

Hashmat Rohian  
CSE 6111

# Motivation

To compress or not to compress, that is the question!

- reducing the space required to store files on disk or tape
- reducing the time to transmit large files.

Image Source : [plus.maths.org/issue23/features/data/data.jpg](http://plus.maths.org/issue23/features/data/data.jpg)

## Example:

- A file with 100K characters

| Character                | a   | b   | c   | d   | e   | f   |
|--------------------------|-----|-----|-----|-----|-----|-----|
| Frequency<br>(in 1000s)  | 45  | 13  | 12  | 16  | 9   | 5   |
| Fixed-length<br>codeword | 000 | 001 | 010 | 011 | 100 | 101 |

$$\begin{aligned}\text{Space} &= (45*3 + 13*3 + 12*3 + 16*3 + 9*3 + 5*3) * 1000 \\ &= \mathbf{300K \text{ bits}}\end{aligned}$$

Can we do better ??

**YES !!**

- Use **variable-length** codes instead.
- Give frequent characters short codewords, and infrequent characters long codewords.

|                             | a   | b   | c   | d   | e    | f    |
|-----------------------------|-----|-----|-----|-----|------|------|
| Frequency<br>(in 1000s)     | 45  | 13  | 12  | 16  | 9    | 5    |
| Fixed-length<br>codeword    | 000 | 001 | 010 | 011 | 100  | 101  |
| Variable-length<br>codeword | 0   | 101 | 100 | 111 | 1101 | 1100 |

$$\begin{aligned}\text{Space} &= (45*1 + 13*3 + 12*3 + 16*3 + 9*4 + 5*4) * 1000 \\ &= \mathbf{224K \text{ bits}} \quad (\text{Savings} = 25\%)\end{aligned}$$

## **PREFIX-FREE CODE :**

- No codeword is also prefix of some other codeword.

**No Ambiguity !!**

|                             |   |     |     |     |      |      |
|-----------------------------|---|-----|-----|-----|------|------|
| Variable-length<br>codeword | 0 | 101 | 100 | 111 | 1101 | 1100 |
|-----------------------------|---|-----|-----|-----|------|------|

## Representation:

The Huffman algorithm is represented as:

- binary tree
- each edge represents either
  - 0, "go to the left child"
  - 1, "go to the right child"
- each leaf corresponds a particular code.
- Cost of the tree
  - $B(T) = \sum f(c) d_T(c)$  where  $c \in C$

## Optimal Code

- Always a **full binary tree**
  - *One leaf for each letter of the alphabet*

## **Constructing a Huffman code**

- *Build the tree  $T$  in a bottom-up manner.*
  - *Begins with a set of  $|C|$  leaves*
  - *Upward  $|C| - 1$  "merging" operations*

### ***Greedy Choice?***

- *The two smallest nodes are chosen at each step.*

## The steps of Huffman's algorithm

f:5 e:9 c:12 b:13 d:16 a:45

## **Running Time Analysis**

$Q$  is implemented as a binary min-heap.

The *merge operation* is executed exactly  $|n| - 1$  times. Each heap operation requires time  $O(\log n)$ .  
 $= O(n \log n)$

- Huffman code

**E = 01**

**I = 00**

**C = 10**

**A = 111**

**H = 110**

- Input

- ACE

- Output

- (111)(10)(01) = 1111001

## Huffman Coding Example

- Decoding
  1. Read compressed file & binary tree
  2. Use binary tree to decode file
    - Follow path from root to leaf

Huffman Decoding 7

- Induction on the number of code words
- The Huffman algorithm finds an optimal code for  $n = 1$
- Suppose that the Huffman algorithm finds an optimal code for codes size  $n$ , now consider a code of size  $n + 1 \dots$

**Correctness proof**

## Greedy Choice Proof

Assume that  $f[a] < f[b]$  and  $f[x] < f[y]$

Since  $f[x]$  and  $f[y]$  are the two lowest frequencies,

$f[x] < f[a]$  and  $f[y] < f[b]$ .

- T – Tree constructed by Huffman
- X – Any code tree
- Show  $C(T) \leq C(X)$
- T' and X' – Trees from the greedy choice
- $C(T') = C(T)$
- $C(X') \leq C(X)$
- T'' and X'' – Trees with minimum cost leaves x and y removed

**Finish the induction proof**

- $C(X'') = C(X') - x - y$
- $C(T'') = C(T') - x - y$
- $C(T'') \leq C(X'')$
- $C(T) = C(T')$
- $= C(T'') + x + y$
- $\leq C(X'') + x + y$
- $= C(X')$
- $\leq C(X)$

**X : Any tree, X': – modified,  
X'' : Two smallest leaves removed**

A photograph of a paved path in a park. The path is flanked by a dense green hedge on the left and a black metal fence on the right. The path leads into the distance, surrounded by lush green trees and foliage. The sky is bright and slightly hazy. The text "What is our next step?" is overlaid in a green, serif font in the center of the image.

What is  
our  
next  
step?

## Challenges and how to tackle them?

Two passes over the data:

- One pass to collect frequency counts of the letters
- A second pass to encode and transmit the letters, based on the static tree structure.

Problems:

Delay (network communication, file compression applications)

Extra disk accesses slow down the algorithm.

We need one-pass methods, in which letters are encoded “***on the fly***”.

## Dynamic Huffman codes

### Algorithm FGK

- The next letter of the message is encoded on the basis of a Huffman tree for the previous letters.
- Encoding length =  $(2S + t)$ , where  $S$  is the encoding length by a static Huffman code, and  $t$  is the number of letters in the original message.

### Sender and receiver

- start with the same initial tree
- use the same algorithm to modify the tree after each letter is processed and thus always have equivalent copies of it.

## Sibling Property:

A binary tree with  $p$  leaves of nonnegative weight is a Huffman tree iff

- the  $p$  leaves have nonnegative weights  $w_1, \dots, w_p$ , and the weight of each internal node is the sum of the weights of its children; and
- the nodes can be numbered in non-decreasing order by weight, so that nodes  $(2j - 1)$  and  $2j$  are siblings, for  $1 \leq j \leq p - 1$ , and their common parent node is higher in the numbering.

## Difficulty

Suppose that  $\mathcal{M}_T = a_{i1}, a_{i2}, \dots, a_{it}$ , has already been processed.

$a_{i(t+1)}$  is encoded and decoded using Huffman tree for  $\mathcal{M}_T$ .

How to modify this tree quickly in order to get a Huffman tree for  $\mathcal{M}_{T+1}$ ?

Eg. Assume  $t = 32$ ,

$a_{i(t+1)} = \text{"b"}$

## First phase

- Begin with the leaf of  $a_{i(t+1)}$ , as the current node.
- Repeatedly interchange the contents of the current node, including the subtree rooted there, with that of the highest numbered node of the same weight
- Make the parent of the latter node the new current node.
- Halt when the root is reached.

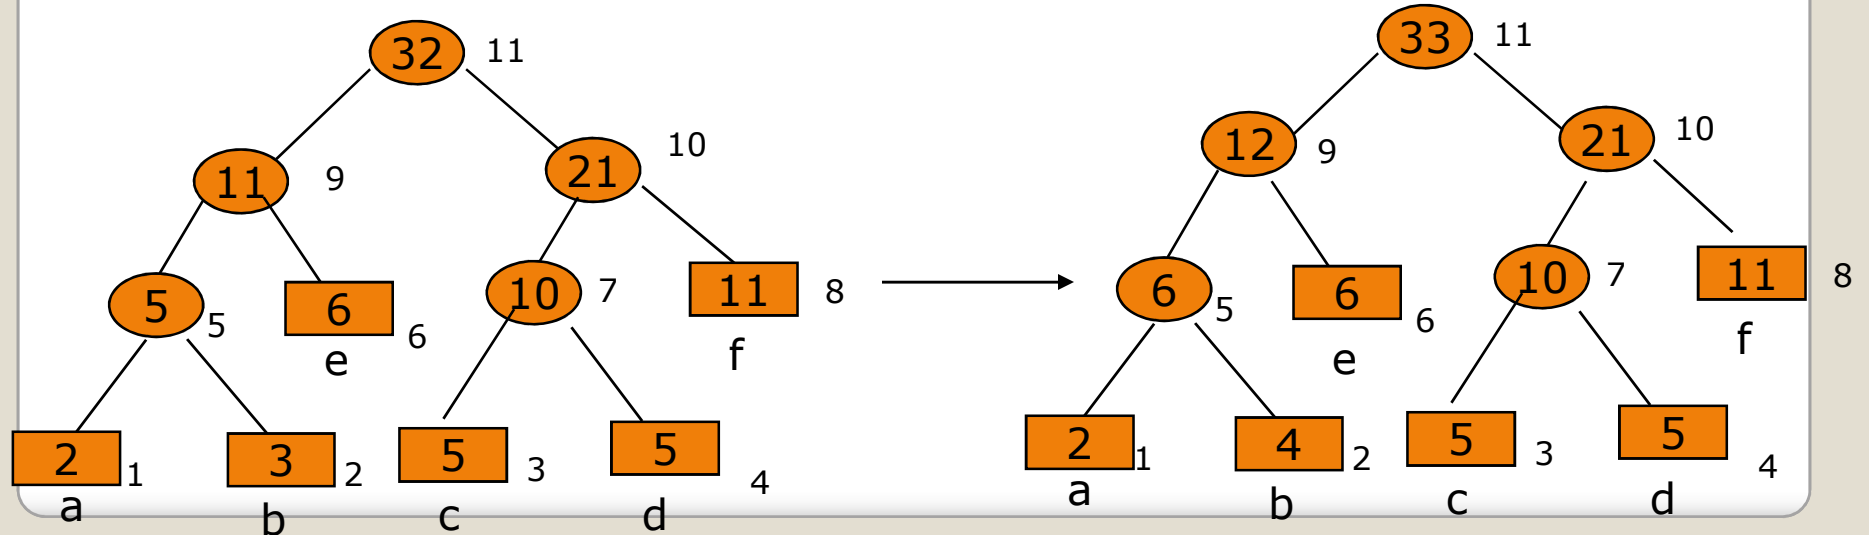

Eg. Assume  $t = 32$ ,  $a_{i(t+1)} = "b"$

## Second phase

- We turn this tree into the desired Huffman tree for  $\mathcal{M}_{T+1}$  by incrementing the weights of  $a_{i(t+1)}$ 's leaf and its ancestors by 1

- Huffman savings are between 20% - 90%
- Dynamic Huffman Coding optimal and efficient
- Optimal data compression achievable by a character code can always be achieved with a prefix code.
- Better compression possible (depends on data)
  - Using other approaches (e.g., pattern dictionary)

## Conclusions

**Thank you for your  
attention!**
